## 2 Profile Likelihood

The term "profile likelihood" can mean multiple things.

In all cases, this is a way to assess uncertainty (or get a point estimate) in a portion of the parameter while essentially ignoring the others.

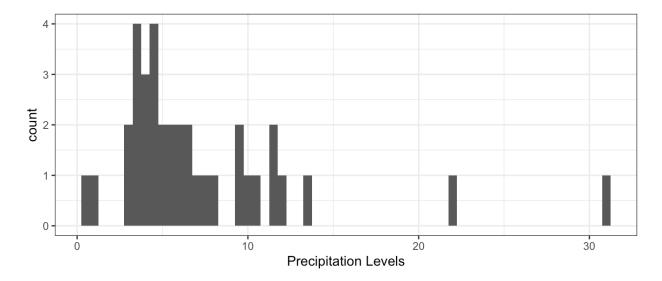

## 2.1 Analytical Methods via Profile Likelihoods

In certain problems it is possible to maximize the log likelihood for part of  $\boldsymbol{\theta} = (\boldsymbol{\theta}_1^{\top}, \boldsymbol{\theta}_2^{\top})^{\top}$  without actually knowing the value of the other part.

Say  $\tilde{\Phi}_{a}(\Phi_{1})$  maximizes the log-likelihood for any value of  $\Phi_{1}$ i.e. for any value  $\Phi_{1}$ ,  $\tilde{\Phi}_{2}(\Phi_{1})$  maximizes the likelihood wort  $\Phi_{2}$ .

The **profile likelihood** is the usual likelihood with the known function of part of the likelihood part of the likelihood only a function of one part of the vector.  $\beta_2$ 

i.e. the profile likelihood is  $L(\underline{\theta}_1, \underline{\widetilde{\theta}}_2(\underline{\theta}_1))$  is a function of if  $\underline{\theta}_1$  (lower dimension). Then we read only maximize  $L(\underline{\theta}_1, \underline{\widetilde{\theta}}_2(\underline{\theta}_1))$  wit  $\underline{\theta}_1$  the get  $\underline{\widehat{\theta}}_1 \Longrightarrow \underline{\widehat{\theta}}_2 = \underline{\widetilde{\theta}}_2(\underline{\widehat{\theta}}_1)$ . In this case we are assuming we can write  $\underline{\widetilde{\theta}}_2(\underline{\theta}_1)$  out as an analytical function (at the MLE). **Example (Hurricane Data, Cont'd):** For 36 hurricanes that had moved far inland on the East Coast of the US in 1900-1969, maximum 24-hour precipitation levels during the time they were over mountains.

We modeled the precipitation levels with a gamma distribution, which has log likelihood

$$\ell(lpha,eta) = -n\log\Gamma(lpha) - nlpha\logeta + (lpha-1)\sum\log Y_i - rac{\sum Y_i}{eta}$$

Taking a partial derivative with  $\beta$ :  $\frac{\partial l(\alpha, \beta)}{\gamma \beta} = S_{\alpha}(\alpha, \beta) = -\frac{n\alpha}{\beta} + \frac{\sum Y_{i}}{\beta^{2}} = 0$   $\implies \widetilde{\beta}(\alpha) = \frac{\overline{Y}}{\gamma} \quad \text{and we can substitute this back into } l(\alpha, \beta):$ 

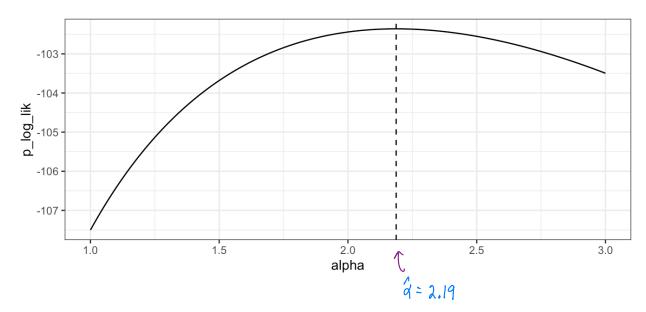

$$l(d, \tilde{\beta}(d)) = -n \log \Gamma(d) - nd (\log \overline{\gamma} - \log d) + (\alpha - 1) \geq \log \gamma_i - nd$$

" profile log - Likelihood

```
gamma_prof_loglik <- function(alpha, data) {
    beta <- mean(data) / alpha
    sum(dgamma(data, alpha, scale = beta, log = TRUE))
    }

    ## get maximum profile likelihood estimate
    alpha_mple <- optim(1, gamma_prof_loglik, data = hurr_rain,
method = "BFGS", control = list(fnscale = -1))

    ## plot profile likelihood
    data.frame(alpha = seq(1, 3, length.out = 200)) |>
    rowwise() |>
    mutate(p_log_lik = gamma_prof_loglik(alpha, hurr_rain)) |>
    ggplot() +
    geom_line(aes(alpha, p_log_lik)) +
    geom_vline(aes(xintercept = alpha_mple$par), lty = 2)
```

$$\Rightarrow \beta = \frac{7.29}{2.19} = 3.33$$

Same values we found before by maximizing.  $l(a, \beta)$  in a dimensions, but we only needed to optimize a function in 1 dimension.

## 2.2 Numerical Methods via Profile Likelihoods

The log likelihood can be maximized over one portion of the partition  $\boldsymbol{\theta} = (\boldsymbol{\theta}_1^{\top}, \boldsymbol{\theta}_2^{\top})^{\top}$  for any fixed value of the other, even if that maximization cannot be expressed as an explicit function.

Ly in other words, this can still be useful if both optimizations are done numerically!

This is the most commonly found situation for profile likelihood methods. more formally

We can'define a profile likelihood as

$$L^p(\boldsymbol{ heta}_{\mathbf{l}}) = \max_{\boldsymbol{ heta}_{\mathbf{l}}} L(\boldsymbol{ heta}_1, \boldsymbol{ heta}_2).$$
 for any  $\boldsymbol{ heta}_{\mathbf{l}} \in \boldsymbol{ heta}_1$ 

Then the log profile hildihood is

$$\mathcal{L}^{\mathsf{P}}(\underline{\theta}_{1}) = \max_{\underline{\theta}_{2}} \log \mathbb{L}(\underline{\theta}_{1}, \underline{\theta}_{2}).$$

The profile likelihood and log profile likelihood behave in many ways like true likelihood functions:

1. The estimate of  $\theta_1$  found by maximizing  $L^p(\theta_2)$  is the MLE of  $\theta_2$ .

$$\max \begin{array}{l} \left( \begin{array}{c} \mu \\ \theta \\ \theta \\ \end{array} \right) = \max \max \max L\left( \begin{array}{c} \theta \\ \theta \\ \theta \\ \end{array} \right) \\ = \max L\left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \theta \\ \end{array} \right) \\ \left( \begin{array}{c} \theta \\ \end{array} \right)$$

2. A likelihood ratio test statistics formed with the profile likelihood has a limiting  $\chi^2$  distribution.

For 
$$\dim(\underline{\theta}_{2}) = p-r$$
  
 $\dim(\underline{\theta}_{1}) = r$   
 $T(\underline{\theta}_{1}) = -2\left[\mathcal{L}(\underline{\theta}_{1}') - \mathcal{L}(\underline{\theta}_{1,m,\varepsilon})\right] \longrightarrow d\chi_{r}^{2}$  for any fixed  $\underline{\theta}_{1}^{\circ} \mathcal{E} \mathcal{E} \mathcal{H} \mathcal{H},$   
 $= \mathcal{L}(\underline{\theta}_{1,m,\varepsilon}, \underline{\theta}_{2,m,\varepsilon}).$ 

## 3. A profile likelihood confidence region is a valid approximate confidence region for $\theta_{\mathbf{p}}$ .

$$C\mathbb{I}: \left\{ \underline{\theta}_{i}^{\circ}: -2\left[ \mathcal{L}^{\prime}(\underline{\theta}_{i}^{\circ}) - \mathcal{L}^{\prime}(\underline{\theta}_{i,\mathsf{MLE}}^{2}) \right] \leq \chi^{2}_{r,i-\alpha} \right\}$$

Where does this confidence region come from?

This is an inverted profile likelihood ratio test.  
Let 
$$r=1$$
, then lank at the profile Likelihood ratio test: ...Ho:  $\mathcal{G}_{1}^{\circ}$  is the true parameter.  
Then  $\lambda = -\lambda \left[ l^{\rho}(\theta_{1}^{\circ}) - l^{\rho}(\hat{\theta}_{i,me}) \right] \sim \chi_{1}^{2}$  asymptotically based on properties of LRT.  
 $P(-\lambda \left[ l^{\rho}(\theta_{1}^{\circ}) - l^{\rho}(\hat{\theta}_{i,me}) \right] > q_{0.95}) \approx 0.05$   
 $\Rightarrow -\lambda \left[ l^{\rho}(\theta_{1}^{\circ}) - l^{\rho}(\hat{\theta}_{i,me}) \right] > 3.84$   
 $l^{\rho}(\theta_{1}^{\circ}) - l^{\rho}(\hat{\theta}_{i,me}) < -1.92$   
 $l^{\rho}(\theta_{1}^{\circ}) - l^{\rho}(\hat{\theta}_{i,me}) - 1.92$   
 $L^{\rho}(\theta_{1}^{\circ}) - l^{\rho}(\hat{\theta}_{i,me}) - 1.92$ 

However, these are *not* full likelihood functions.

The derivatives of profile likelihoods don't behave like the derivatives of full likelihoods, e.g.  

$$E \frac{\partial L^{p}(\underline{\sigma}_{1})}{\partial \underline{\sigma}_{1}} \neq 0 \quad \text{necessarily}!$$

When we hold the fixed, the uncertainty in estimator of the is ignored in the uncertainty of estimation of the

=> There is not a "Wald-type" (Normal) theory for postile likelihood estimates.
